

Natural joins allow the selection from two tables without the need to write a complex where clause ...

```
Worksheet Query Builder
select b.sd_section_name
      ,a.si_stock_number
      ,a.si_stock_description
from stock_information a
natural join section_details b
```

Here, the join is based on columns with the same name in both tables, this can be quite a problem if audit columns are named the same as well as the key columns !
